

# Atariage batari basic

Atariage batari basic

The batari Basic programming language now has a new home at github.

For the latest batari Basic (v1.2 at the time of this writing) you can visit the batari Basic release page. The page where I hosted the now-defunct "reveng" fork now points to that release page.

Feel free to comment or ask questions about this change. If you have bug reports, I'd ask that they be submitted to either github or the AA bB bug report thread, and not brought up in this thread. I'd prefer github issues be used (since everything is tracked, conversations about bugs are threaded, etc) but I completely understand that not everybody wants to have a github account.

Lastly, 7800basic will be getting the same treatment. I just need a break, as the cleanup and prep for the bB move took more effort than expected.

Great job! This is an important step for BB's future. It's going to be so good to have it all consolidated to one place, and GitHub is the goto repository for most code development these days.

Here are a few questions:

Is the Unofficial MacOS 64-bit bB build included?

Should the bB page at my web site link to GitHub instead of the bB with native 64k cart support - 1.1d.reveng thread?

Should you change the title of this thread from "official home for batari Basic to "Official Home for batari Basic" so it will look better?

Is bataribasic going away?

I'll also update Atari Dev Studio once I get back from holidays.

Thanks for the support, Omegamatrix and mksmith!
