Electric source

Energy Information Administration - EIA - Official Energy Statistics from the U.S. ...

Electricity is a secondary energy source that is generated (produced) from primary ...

Statista R identifies and awards industry leaders, top providers, and exceptional brands through exclusive rankings and top lists in collaboration with renowned media brands worldwide. For more details, visit our website.

In the United States, electricity derived from coal has decreased over the past two decades, with the annual output declining by almost 63 percent between 2010 and 2023. In contrast, there has been a rise in natural gas and renewable sources within the energy mix.

Most electricity in the U.S. is generated from steam turbines, which can be powered by fossil and nuclear fuels, biomass, geothermal, and solar thermal energy. Other systems such as gas turbines, hydro turbines, wind turbines, and solar photovoltaics are also major generation technologies. Electric utilities in the U.S. generated more than 2,176 terawatt hours in 2023, accounting for just over half of the power output in the country that year.

Renewable sources have become more prominent in the U.S. in recent years, particularly wind, hydro, and solar energy. The former has overtaken conventional hydropower, becoming the leading renewable energy source in the U.S. since 2019. Wind and solar power have also accounted for the largest share of electricity capacity additions in the country.

Fossil fuels remain the greatest source of electricity generation worldwide. In 2023, coal accounted for roughly 35.5 percent of the global power mix, while natural gas followed with a 23 percent share. China, India, and the United States accounted for the largest share of coal used for electricity generation.

Fossil fuel use notwithstanding, the share of renewables in global electricity has seen a more pronounced year-on-year growth in recent years, following increased efforts by governments to combat global warming and a decrease in levelized costs. Projections indicate that renewables will surpass fossil fuels as the main power source by 2040.

China is the largest electricity consumer in the world, requiring more than 8,000 terawatt-hours of electricity every year. However, this economic power accounts for the largest population in the world and its electricity

Electric source

consumption per capita is almost tenfold smaller than the consumption of Iceland, although the power used in this country came almost completely from clean sources.
