

Hot water solar system

Hot water solar system

Six steps to solar hot water installation

Learn how to cut as much as 80% off your water-heating bills.

Solar hot water systems are a great way to save money and decrease your environmental impact. These systems use the sun's energy to heat water, reducing your reliance on fossil fuels and lowering your utility bills. In this guide, we'll explore how solar hot water systems work, their benefits, and what you should consider before installing one.

Solar hot water systems typically consist of solar collectors, a storage tank, and sometimes a pump and controller. The basic principle is simple--solar collectors absorb heat from the sun and transfer it to water, which is then stored for later use.

These systems can provide up to 80% of a household's hot water needs, depending on factors such as climate, system size, and hot water usage patterns. They come in two main types: active and passive. Each type has its own method of circulating water or heat transfer fluid through the system.

Active systems use pumps and controllers to circulate water or heat-transfer fluid through the solar collectors. These systems are more complex but offer greater control and efficiency, especially in colder climates. There are two types of active systems:

Passive systems rely on natural convection to circulate water through the system, without the need for pumps. While generally less efficient than active systems, they're often more reliable and can last longer due to fewer moving parts. These are the two main types of passive systems:

The heart of any solar hot water system is the solar collector. Two main types are typically used: flat-plate collectors and evacuated tube collectors.

Flat-plate collectors are the most common type used in solar hot water systems. They consist of an insulated, weatherproof box containing a dark absorber plate under one or more transparent covers. These collectors can be used in both warm and cold climates. Key features include:

Evacuated tube collectors are more efficient than flat-plate collectors, especially in cold climates or on cloudy days. They consist of rows of glass tubes, each containing an absorber plate within a vacuum-sealed environment. Some pros of evacuated tube collectors include:

Installing a solar hot water system offers a range of benefits, which we'll explore in detail below.

Hot water solar system

One of the biggest perks of solar hot water systems is major energy bill savings. By harnessing free solar energy, these systems can reduce water heating costs by 50% to 80% across a 20-year lifespan. Over time, you can often recoup your initial investment through these savings. Payback periods typically range from 5 to 10 years, depending on factors such as system size, local energy costs, and available incentives.
