Ireland solar thermal energy

Solar panels work both on sunny and cloudy days. They not only harness direct sunlight when the sky is clear but also diffused light on the cloudy days, so you will still be generating electricity though not as much as on a sunny day.

One of the problems with solar energy is that it is intermittent, depending on the climate or time: sunny or not, day or night. The solution to this is energy storage and although it is still a new topic we can see many advances in this area of research. Today, energy storage is done through batteries and they can range from a simple car battery to more sophisticated backup systems. Another solution is "net-metering". In general terms this means using the electricity grid as a storage option. So, owners of solar panels can feed the extra electricity generated during sunny days into the electricity grid and then, during the night or on cloudy days, use electricity from the grid. The downside of this is that the grid supply is generally from power plants using fossil fuels.
