

Types of energy storage portugal

As such, the Portuguese energy industry recognises the crucial role in which energy storage can play in the energy transition in order to properly integrate renewable energy generation into the grid. The co-location of energy storage systems with existing generation, especially renewable plants, has been growing rapidly in recent years.

Concerning the current status of energy storage in Portugal, there is still a renewable energy surplus in the range of 800-1200 GW h (Miguel et al., 2018) that is lost, mainly in Winter and Spring. Pumped hydro, based on reverse pumping systems installed in the large hydro plants is currently the dominant form of energy storage.

The Azores" and Madeira"s programmes to support the energy transition appear to be more ambitious than those for mainland Portugal, and these island regions can pioneer living labs to test innovative solutions, like storage, smart grids, electric mobility and integration of very high shares of renewables.

A storage facility can take two different forms: (1) autonomous storage, where the facility has a direct connection to the RESP and is not associated with an electricity power station or a Production Unit for Self-Consumption (UPAC); or (2) associated storage, where the installation has no direct connection to the RESP and is associated with a ...

The configuration of a solar photovoltaic system integrating energy storage in Portugal is yet unclear in the technical, energetic and economic point of view. The energy management jointly with the battery operation have great influence in the system configuration"s profitability value.

The European Commission"s European Green Deal has established the roadmap for reducing emissions by at least 55 per cent. Renewable energies are inevitably vulnerable to variations in availability, since the sun and the wind cannot be programmed. Energy storage is therefore essential if EU targets are to be met.

Portugal"s installed energy storage capacity is still predominantly based on hydro pumping, which currently stands at 4,164 GW year.[1] However, this paradigm is about to change with the democratisation of energy

storage solutions through wind and solar production.

Storage solutions other than hydroelectric production have been included in the electricity sector legislation since 2019. They have also been considered in competitive procedures for the allocation of injection capacity in the public electricity service network (RESP) or for the purposes of graduating the projects in agreements with the network operator.
